

Banking Memory

Financial Memory Layer for AI Agents.

AI agents can't operate on financial data they don't truly understand

Financial context is fragmented

Bank transactions, accounts, invoices, spreadsheets, rules, and internal decisions live in different places. AI agents can answer questions, but they often lack the full context behind the numbers.

Financial data must be precise

Companies and people don't use financial data for curiosity. They use it to make daily decisions. A wrong answer can create real operational damage.

Generic AI is not enough for daily finance

Without persistent memory and domain-specific skills, every query starts from zero.

Bank data is connected. Financial understanding is not.

How It Works

Plaid brings the bank data. Cognition turns it into persistent financial memory. Skills make it usable by agents.

1

Banking data layer

Plaid connects bank accounts and brings raw financial data into the system.

2

Ingestion layer

Raw transactions and documents are cleaned, structured, and prepared for memory.

3

Memory Graph

Cognition stores the financial context as a queryable knowledge graph, connecting accounts, transactions, entities, and patterns.

4

Agent layer

AI agents query the memory, detect missing context, improve the graph, and use skills to act on the data.

From bank data → to structured memory → to financial reasoning → to agent action.

Cognition v1.0

Plaid API

CLAUDE / LLM

Agent Skills: npm for LLM Context

Skills are modular instruction packs that give LLM agents expert-level knowledge of specific domains — bundled with real specs, examples, and best practices.
